#### Fine-tuning simulation conditions using gmse\_apply

Here we demonstrate how simulations in GMSE can be more fine-tuned to specific empirical situations through the use of gmse\_apply. To do this, we use the same scenario described in SI3; we first recreate the basic scenario run in gmse using gmse\_apply, and then build in additional modelling details including (1) custom placement of user land, (2) parameterisation of individual user budgets, and (3) density-dependent movement of resources. We emphasise that these simulations are provided only to demonstrate the use of GMSE, and specifically to show the flexibility of the gmse\_apply function, not to accurately recreate the dynamics of a specific system or make management recommendations.

We reconsider the case of a protected waterfowl population that exploits agricultural land (e.g., Fox and Madsen, 2017; Mason et al., 2017; Tulloch et al., 2017; Cusack et al., 2018). The manager attempts to keep the watefowl at a target abundance, while users (farmers) attempt to maximise agricultural yield on the land that they own. We again parameterise our model using demographic information from the Taiga Bean Goose (Anser fabalis fabalis), as reported by Johnson et al. (2018) and AEWA (2016). Relevant parameter values are listed in the table below.

Table 1: GMSE simulation parameter values inspired by Johnson et al. (2018) and AEWA (2016)

Parameter	Value	Description
remove_pr	0.122	Goose density-independent mortality probability
lambda	0.275	Expected offspring production per time step
res_death_K	93870	Goose carrying capacity (on adult mortality)
RESOURCE_ini	35000	Initial goose abundance
manage_target	70000	Manager's target goose abundance
res_death_type	3	Mortality (density and density-independent sources)

Additionally, we continue to use the following values for consistency, except in the case of stakeholders, where we reduce the number of farmers to stakeholders = 8. This is done to for two reasons. First, it speeds up simulations for the purpose of demonstration; second, it makes the presentation of our custom landscape ownership easier to visualise (see below).

Table 2: Non-default GMSE parameter values chosen by authors

Parameter	Value	Description
manager_budget user_budget	10000 10000	Manager's budget for setting policy options Users' budgets for actions
<pre>public_land</pre>	0.4	Proportion of the landscape that is public

Parameter	Value	Description	
stakeholders	8	Number of stakeholders	
land_ownership	TRUE	Users own landscape cells	
res_consume	0.02	Landscape cell output consumed by a resource	
observe_type	3	Observation model type (survey)	
agent_view	1	Cells managers can see when conducting a survey	

All other values are set to GMSE defaults, except where specifically noted otherwise.

#### Re-creating gmse simulations using gmse\_apply

We now recreate the simulations in SI3, which were run using the gmse function, in gmse\_apply. Doing so requires us to first initialise simulations using one call of gmse\_apply, then loop through multiple time steps that again call gmse\_apply; results of interest are recorded in a data frame (sim\_sum\_1). Following the protocol introduced in SI2, we can call the initialising simulation sim\_old, and use the code below to read in the relevant parameter values.

Note that the argument <code>get\_res = "Full"</code> causes <code>sim\_old</code> to retain all of the relevant data structures for simulating a new time step and recording simulation results. This includes the key simulation output, which is located in <code>sim\_old\$basic\_output</code>, which is printed below.

```

We can then loop over 30 time steps to recreate the simulations from SI3. In these simulations, we are specifically interested in the resource and observation outputs, as well as the manager policy and user actions for culling, which we record below in the data frame sim\_sum\_1. The inclusion of the argument old\_list tells gmse\_apply to use parameters and values from the list sim\_old in the new time step.

The above output from sim\_sum\_1 shows the data frame that holds the information we were interested in pulling out of our simulation results. All of this information was available under the list element sim\_new\$basic\_output, but other list elements of sim\_new might also be useful to record. It is important to remember that this example of gmse\_apply is using the default resource, observation, manager, and user sub-models. Custom sub-models could produce different outputs in sim\_new (see SI2 for examples). For default sub-models, there are some list elements that might be especially useful. These elements can potentially be edited within the above loop to dynamically adjust simulations. For more explanation of built-in GMSE data arrays, see SI7.

- sim\_new\$resource\_array: A table holding all information on resources. Rows correspond to discrete resources, and columns correspond to resource properties: (1) ID, (2-4) types (not currently in use), (5) x-location, (6) y-location, (7) movement parameter, (8) time, (9) density independent mortality parameter (remove\_pr), (10) reproduction parameter (lambda), (11) offspring number, (12) age, (13-14) observation columns, (15) consumption rate (res\_consume), and (16-20) recorded experiences of user actions (e.g., was the resource culled or scared?).
- sim\_new\$AGENTS: A table holding basic information on agents (manager and users). Rows correspond to a unique agent, and columns correspond to agent properties: (1) ID, (2) type (0 for the manager, 1 for users), (3-4) additional type options not currently in use, (5-6), x and y locations (usually ignored), (7) movement parameter (usually ignored), (8) time, (9) agent's viewing ability in cells (agent\_view), (10) error parameter, (11-12) values for holding marks and tallies of resources, (13-15) values for holding observations, (16) yield from landscape cells, (17) budget (manager\_budget and user\_budget).
- sim\_new\$observation\_vector: Estimate of total resource number from the observation model (observation\_array also holds this information in a different way depending on observe\_type)
- sim\_new\$LAND: The landscape on which interactions occur, which is stored as a 3D array with land\_dim\_1 rows, land\_dim\_2 columns, and 3 layers. Layer 1 (sim\_new\$LAND["1]) is not currently used in default sub-models, but could be used to store values that affect resources and agents. Layer 2 (sim\_new\$LAND["2]) stores crop yield from a cell, and layer 3 (sim\_new\$LAND["3]) stores the owner of the cell (value corresponds to the agent's ID).
- sim\_new\$manage\_vector: The cost of each action as set by the manager. For even more fine-tuning, individual costs for the actions of each agent can be set for each user in sim\_new\$manager\_array.
- sim\_new\$user\_vector: The total number of actions performed by each user. A more detailed breakdown of actions by individual users is held in sim\_new\$user\_array.

Next, we show how to adjust the landscape to manually set land ownership in gmse\_apply.

### 1. Custom placement of user land

By default, all farmers in GMSE are allocated the same number of landscape cells, which are simply placed in order of the farmer's ID. Public land is produced by placing landscape cells that are technically owned by the manager, and therefore have landscape cell values of 1. The image below shows this landscape for the eight farmers from sim\_old.

```
image(x = sim_old$LAND[,,3], col = topo.colors(9), xaxt = "n", yaxt = "n");
```

We can change the ownership of cells by manipulating sim\_old\$LAND["3]. First we initialise a new sim\_old below.

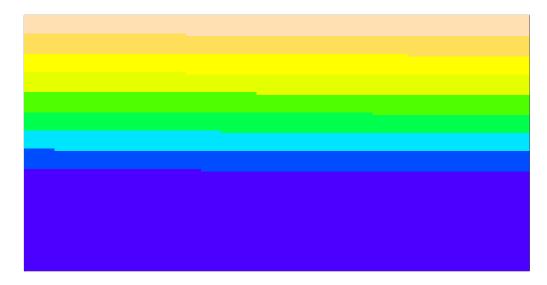

Figure 1: Default position of land ownership by farmers.

```
manage_target = 70000, res_death_type = 3,
manager_budget = 10000, user_budget = 10000,
public_land = 0.4, stakeholders = 8, res_consume = 0.02,
res_birth_K = 200000, land_ownership = TRUE,
observe_type = 3, agent_view = 1, converge_crit = 0.01,
ga_mingen = 200);
```

Because we have not specified landscape dimensions in the above, the landscape reverts to the default size of 100 by 100 cells. We can then manually assign landscape cells to the eight farmers, whose IDs range from 2-9 (ID value 1 is the manager). Below we do this to make eight different sized farms.

```
1:20,
                            3] <- 2;
sim_old$LAND[1:20,
sim_old$LAND[1:20,
                            3] <- 3;
                   21:40.
sim_old$LAND[1:20,
                   41:60,
                           3] <- 4;
sim_old$LAND[1:20,
                   61:80, 3] <- 5;
sim_old$LAND[1:20, 81:100, 3] <- 6;
sim_old$LAND[21:40, 1:50, 3] <- 7;
sim_old$LAND[21:40, 51:100, 3] <- 8;
sim old$LAND[41:60, 1:100, 3] <- 9;
sim_old$LAND[61:100, 1:100, 3] <- 1; # Public land
image(x = sim_old$LAND[,,3], col = topo.colors(9), xaxt = "n", yaxt = "n");
```

The above image shows the modified landscape stored in sim\_old, which can now be incorporated into simulations using gmse\_apply. We can think of all the plots on the left side of the landscape as farms of various sizes, while the blue area of the landscape on the right is public land.

# 2. Parameterisation of individual user budgets

Perhaps we want to assume that farmers have different budgets, which are correlated in some way to the number of landscape cells that they own. Custom user budgets can be set by manipulating sim\_old\$AGENTS, the last column of which (column 17) holds the budget for each user. Agent IDs (as stored on the landscape above) correspond to rows of sim\_old\$AGENTS, so individual budgets can be directly input as desired. We can do this manually (e.g., sim\_old\$AGENTS[2, 17] <- 4000), or, alternatively, if farmer budget positively

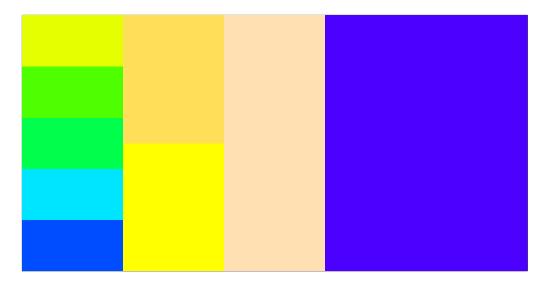

Figure 2: Land ownership by farmers as customised in gmse\_apply.

correlates to landscape owned, we can use a loop to input values as below.

The number of cells owned by the manager (1) and each farmer (2-8) is therefore listed in the table below.

ID	1	2	3	4	5	6	7	8	9
${f Budget}$	10000	4000	4000	4000	4000	4000	10000	10000	20000

As with sim\_old\$LAND values, changes to sim\_old\$AGENTS will be retained in simulations looped through gmse\_apply.

# 3. Density-dependent movement of resources

Lastly, we consider a more nuanced change to simulations, in which the rules for movement of resources are modified to account for density-dependence. Assume that geese tend to avoid aggregating, such that if a goose is located on the same cell as too many other geese, then it will move at the start of a time step. Programming this movement rule can be accomplished by creating a new function to apply to the resource data array sim\_old\$resource\_array. Below, a custom function is defined that causes a goose to move up to 5 cells in any direction if it finds itself on a cell with more than 10 other geese. As with default GMSE simulations, movement is based on a torus landscape (where no landscape edge exists, so that if resources move off of one side of the landscape they appear on the opposite side). We will use this custom function to modify sim\_old\$resource\_array prior to running gmse\_apply, thereby modelling a custom-built process affecting resource distribution that is integrated into GMSE.

```
avoid_aggregation <- function(sim_resource_array, land_dim_1 = 100,
                                 land_dim_2 = 100){
    goose_number <- dim(sim_resource_array)[1] # How many geese are there?</pre>
    for(goose in 1:goose_number){
                                                     # Loop through all rows of geese
        x_loc <- sim_resource_array[goose, 5];</pre>
        y_loc <- sim_resource_array[goose, 6];</pre>
        shared <- sum( sim_resource_array[,5] == x_loc &</pre>
                         sim_resource_array[,6] == y_loc);
        if(shared > 10){
             new_x \leftarrow x_{loc} + sample(x = -5:5, size = 1);
             new_y \leftarrow y_{loc} + sample(x = -5:5, size = 1);
             if(new_x < 0){ # The 'if' statements below apply the torus
                 new_x <- land_dim_1 + new_x;</pre>
             if(new_x >= land_dim_1){
                 new_x <- new_x - land_dim_1;</pre>
             if(new_y < 0){
                 new_y <- land_dim_2 + new_x;</pre>
             if(new_y >= land_dim_2){
                 new_y <- new_y - land_dim_2;</pre>
             sim_resource_array[goose, 5] <- new_x;</pre>
             sim_resource_array[goose, 6] <- new_y;</pre>
        }
    }
    return(sim_resource_array);
}
```

With the above function written, we can apply the new movement rule along with our custom farm placement and custom farmer budgets to the simulation of goose population dynamics.

### Simulation with custom farms, budgets, and goose movement

Below shows an example of gmse\_apply with custom landscapes, farmer budgets, and density-dependent goose movement rules.

```
# First initialise a simulation
sim_old <- gmse_apply(get_res = "Full", remove_pr = 0.122, lambda = 0.275,
                       res_death_K = 93870, RESOURCE_ini = 35000,
                       manage_target = 70000, res_death_type = 3,
                       manager_budget = 10000, user_budget = 10000,
                       public_land = 0.4, stakeholders = 8, res_consume = 0.02,
                       res_birth_K = 200000, land_ownership = TRUE,
                       observe_type = 3, agent_view = 1, converge_crit = 0.01,
                       ga_mingen = 200, res_move_type = 0);
# By setting `res_move_type = 0`, no resource movement will occur in gmse_apply
# Adjust the landscape ownership below
sim_old$LAND[1:20,
                   1:20, 3] <- 2;
sim old$LAND[1:20, 21:40, 3] <- 3;
sim_old$LAND[1:20, 41:60, 3] <- 4;
sim old$LAND[1:20, 61:80, 3] <- 5;
```

```
sim_old$LAND[1:20, 81:100, 3] <- 6;
sim_old$LAND[21:40, 1:50, 3] <- 7;
sim_old$LAND[21:40, 51:100, 3] <- 8;
sim_old$LAND[41:60, 1:100, 3] <- 9;
sim_old$LAND[61:100, 1:100, 3] <- 1;
# Change the budgets of each farmer based on the land they own
for(ID in 2:9){
                            <- sum(sim old$LAND[,,3] == ID);
    cells owned
    sim_old$AGENTS[ID, 17] <- 10 * cells_owned;</pre>
}
# Begin simulating time steps for the system
sim_sum_2 <- matrix(data = NA, nrow = 30, ncol = 5);</pre>
for(time_step in 1:30){
    # Apply the new movement rules at the beginning of the loop
    sim_old$resource_array <- avoid_aggregation(sim_resource_array =</pre>
                                                        sim_old$resource_array);
    # Next, move on to simulate (old_list remembers that res_move_type = 0)
                             <- gmse_apply(get_res = "Full", old_list = sim_old);</pre>
    sim_new
    sim_sum_2[time_step, 1] <- time_step;</pre>
    sim_sum_2[time_step, 2] <- sim_new$basic_output$resource_results[1];</pre>
    sim_sum_2[time_step, 3] <- sim_new$basic_output$observation_results[1];</pre>
    sim_sum_2[time_step, 4] <- sim_new$basic_output$manager_results[3];</pre>
    sim_sum_2[time_step, 5] <- sum(sim_new$basic_output$user_results[,3]);</pre>
    sim_old
                             <- sim_new;
}
colnames(sim_sum_2) <- c("Time", "Pop_size", "Pop_est", "Cull_cost",</pre>
                          "Cull_count");
print(sim_sum_2);
```

#### Conclusions

In this example, we showed how the built-in resource, observation, manager, and user sub-models can be customised by manipulating the data within the data structures that they use. The goal was to show how software users can work with these existing sub-models and data structures to customise GMSE simulations. Readers seeking even greater flexibility (e.g., replacing an entire built-in sub-model with a custom sub-model) should refer to SI2 that introduces gmse\_apply more generally. Future versions of GMSE are likely to expand on the built-in options available for simulation; requests for such expansions, or contributions, can be submitted to GitHub.
